

The University of the West Indies, Cave Hill Campus

ECON 2025 - Statistical Methods I

Lecture 1: Combinatorial Methods

Tommy Descartes

University of the West Indies, Cave Hill Campus, Economics Department

2026-09-22

Table of contents I

- 1 Introduction
- 2 The Multiplication Rule
- 3 The Multiplication Rule with and without Repetition
- 4 Addition Rule
- 5 Permutation
- 6 Circular Permutation

- 7 Combinations
- 8 Partitioning
- 9 Binomial Coefficients
- 10 Symmetry Property of Binomial Coefficients
- 11 Pascal's Triangle
- 12 Lecture Recap

Section 1

Introduction

Learning Objectives

In statistics, many problems require counting how many outcomes are possible without listing every one of them. This lecture builds the counting toolkit used throughout the rest of the course.

Learning Objectives

By the end of this lecture, students should be able to:

- 1 Apply the multiplication rule of counting, with and without repetition
- 2 Apply the addition rule of counting, and combine it with the multiplication rule
- 3 Distinguish permutations from combinations, and compute each
- 4 Compute permutations of a multiset (repeated/identical objects)
- 5 Compute the number of ways to partition a set into several subsets

Learning Objectives

In statistics, many problems require counting how many outcomes are possible without listing every one of them. This lecture builds the counting toolkit used throughout the rest of the course.

Learning Objectives

By the end of this lecture, students should be able to:

- 1 Apply the multiplication rule of counting, with and without repetition
- 2 Apply the addition rule of counting, and combine it with the multiplication rule
- 3 Distinguish permutations from combinations, and compute each
- 4 Compute permutations of a multiset (repeated/identical objects)
- 5 Compute the number of ways to partition a set into several subsets

Learning Objectives

Learning Objectives

By the end of this lecture, students should be able to:

- 1 Apply the multiplication rule of counting, with and without repetition
- 2 Apply the addition rule of counting, and combine it with the multiplication rule
- 3 Distinguish permutations from combinations, and compute each
- 4 Compute permutations of a multiset (repeated/identical objects)
- 5 Compute the number of ways to partition a set into several subsets

Learning Objectives

In statistics, many problems require counting how many outcomes are possible without listing every one of them. This lecture builds the counting toolkit used throughout the rest of the course.

Learning Objectives

By the end of this lecture, students should be able to:

- ➊ Apply the multiplication rule of counting, with and without repetition
- ➋ Apply the addition rule of counting, and combine it with the multiplication rule
- ➌ Distinguish permutations from combinations, and compute each
- ➍ Compute permutations of a multiset (repeated/identical objects)
- ➎ Compute the number of ways to partition a set into several subsets

Learning Objectives

- 6 Explain the connection between combinations and binomial coefficients
- 7 State and apply the symmetry property of binomial coefficients
- 8 Use Pascal's Triangle to obtain binomial expansion coefficients

Learning Objectives

- 6 Explain the connection between combinations and binomial coefficients
- 7 State and apply the symmetry property of binomial coefficients
- 8 Use Pascal's Triangle to obtain binomial expansion coefficients

Learning Objectives

- 6 Explain the connection between combinations and binomial coefficients

- 8 Use Pascal's Triangle to obtain binomial expansion coefficients

Learning Objectives

- 6 Explain the connection between combinations and binomial coefficients
- 7 State and apply the symmetry property of binomial coefficients
- 8 Use Pascal's Triangle to obtain binomial expansion coefficients

Section 2

The Multiplication Rule

Basic Principle of Counting

EXPERIMENT

- Let us start with a simple experiment that involves 2 stages.
 - ① Stage 1: Choose between 4 modes of transportation to get to UWI.
 - ② Stage 2: Choose between 3 different routes to get to UWI.
- For the experiment to be complete, we must make a choice at each stage.
- **Caveat** - *The choices at each stage are independent of each other.*

QUESTION:

How many different ways can we complete this experiment?

EXPERIMENT

- Let us start with a simple experiment that involves 2 stages.
 - ① Stage 1: Choose between 4 modes of transportation to get to UWI.
 - ② Stage 2: Choose between 3 different routes to get to UWI.
- For the experiment to be complete, we must make a choice at each stage.
- **Caveat** - *The choices at each stage are independent of each other.*

- **Caveat** - *The choices at each stage are independent of each other.*

QUESTION:

How many different ways can we complete this experiment?

Basic Principle of Counting (Cont'd)

Let us set up the problem mathematically.

Mode of Transportation = $S_1 = \{T_1, T_2, T_3, T_4\}$, so $n_1 = |S_1| = 4$

Routes = $S_2 = \{R_1, R_2, R_3\}$, so $n_2 = |S_2| = 3$

Basic Principle of Counting (Cont'd)

Let us set up the problem mathematically.

Mode of Transportation = $S_1 = \{T_1, T_2, T_3, T_4\}$, so $n_1 = |S_1| = 4$

Routes = $S_2 = \{R_1, R_2, R_3\}$, so $n_2 = |S_2| = 3$

Basic Principle of Counting (Cont'd)

Let us set up the problem mathematically.

Mode of Transportation = $S_1 = \{T_1, T_2, T_3, T_4\}$, so $n_1 = |S_1| = 4$

Routes = $S_2 = \{R_1, R_2, R_3\}$, so $n_2 = |S_2| = 3$

Basic Principle of Counting (Cont'd)

Theorem (Multiplication Principle of Counting)

Theorem 1. Multiplication Principle of Counting. If an operation consists of two steps, where the first step can be performed in n_1 ways and the second step can be performed in n_2 ways, then the operation can be performed in $n_1 \times n_2$ ways.

Applying the Multiplication Principle of Counting to our experiment:

$$n_1 \times n_2 = 4 \times 3 = 12$$

So there are 12 different ways to complete the experiment.

Basic Principle of Counting (Cont'd)

Visualizing the experiment using a tree diagram: Tree Diagram

Start

Mode ($n_1 = 4$)

Route ($n_2 = 3$)

- The tree diagram shows all the possible outcomes of the experiment. Each path from the root to a leaf represents a unique combination of choices made at each stage.

Basic Principle of Counting (Cont'd)

Extending beyond the two stage case

If we expand the experiment to include a third stage.

- Stage 3: Choose between 2 of UWI's libraries to study.

$$S_3 = \{L_1, L_2\}, n_3 = |S_3| = 2$$

Applying the multiplication rule to the 3 stage case:

$$n_1 \times n_2 \times n_3 = 4 \times 3 \times 2 = 24$$

- So there are 24 ways to complete the experiment.

Basic Principle of Counting (Cont'd)

Visualizing the 3 stage experiment using a tree diagram:

Tree Diagram

Start

Mode ($n_1 = 4$)

Route ($n_2 = 3$)

Library ($n_3 = 2$)

- The tree diagram shows all the possible outcomes of the experiment. Each path from the root to a leaf represents a unique combination of choices made at each stage.

Basic Principle of Counting (Cont'd)

Visualizing the 3 stage experiment using a tree diagram:

Tree Diagram

Start

Mode ($n_1 = 4$)

Route ($n_2 = 3$)

Library ($n_3 = 2$)

- The tree diagram shows all the possible outcomes of the experiment. Each path from the root to a leaf represents a unique combination of choices made at each stage.

Basic Principle of Counting (Cont'd)

Theorem 2. If an operation consists of k steps, of which the first can be done in n_1 ways, for each of these, the second step can be done in n_2 ways, for each of the first two, the third can be done n_3 ways, and so forth, then the whole operation can be done in,

$$n_1 \cdot n_2 \cdot \dots \cdot n_k$$

ways.

- This is a generalization of the 2 stage multiplication rule

Basic Principle of Counting (Cont'd)

Example

Example

Suppose a family in Barbados is planning a cruise and can depart from either Jamaica or Miami. The family can also choose from four airlines: JetBlue, American Airlines, Delta, and Caribbean Airlines. How many different airline–departure port combinations are possible?

Basic Principle of Counting (Cont'd)

Example

Example

Suppose a family in Barbados is planning a cruise and can depart from either Jamaica or Miami. The family can also choose from four airlines: JetBlue, American Airlines, Delta, and Caribbean Airlines. How many different airline–departure port combinations are possible?

Basic Principle of Counting (Cont'd)

Let the set possible home port be,

$$H = \{Jamaica, Miami\}, \text{ so } n_1 = 2$$

Let the set of airlines be,

$$A = \{JB, AA, DL, CAL\} \text{ so } n_2 = 4$$

Using the multiplication rule, the total # of airline-home-port sequential pairs are:

$$n_1 \times n_2 = (2 \cdot 4) = 8$$

There are therefore **8** possible airline home port ordered pairs.

Basic Principle of Counting (Cont'd)

Start

Home Port ($n_1 = 2$)

Airline ($n_2 = 4$)

JB = JetBlue

AA = American Airlines

DL = Delta

CAL = Caribbean Airline

$n_1 n_2 = 2 \times 4 = 8$ **possible travel arrangements**

Section 3

The Multiplication Rule with and without Repetition

Multiplication Rule with Repetition

- Suppose a security code consists of **4 letters** chosen from the 26 letter of the alphabet.
- If repetition is allowed, the multiplication rule gives,

$$26 \times 26 \times 26 \times 26 = 26^4$$

- Using the multiplication rule above, in how many different ways can a student answer a 20-question true-or-false examination?
- For each question, there are two possible responses:

$$\{\text{True or False}\} = 2^{20} = \boxed{1,048,576}$$

- **Note:** whenever there are the same number of choices at each stage and repetition is allowed the following applies - n^r .

Multiplication Rule with Repetition

- Suppose a security code consists of **4 letters** chosen from the 26 letter of the alphabet.
- If repetition is allowed, the multiplication rule gives,

$$26 \times 26 \times 26 \times 26 = 26^4$$

- Using the multiplication rule above, in how many different ways can a student answer a 20-question true-or-false examination?
- For each question, there are two possible responses:

$$\{\text{True or False}\} = 2^{20} = \boxed{1,048,576}$$

- **Note:** whenever there are the same number of choices at each stage and repetition is allowed the following applies - n^r .

Multiplication Rule with Repetition

- Suppose a security code consists of **4 letters** chosen from the 26 letter of the alphabet.
- If repetition is allowed, the multiplication rule gives,

$$26 \times 26 \times 26 \times 26 = 26^4$$

- For each question, there are two possible responses:

$$\{\text{True or False}\} = 2^{20} = \boxed{1,048,576}$$

- **Note:** whenever there are the same number of choices at each stage and repetition is allowed the following applies - n^r .

Multiplication with repetition

- Pictorial representation of multiplication with repetition.

Where n is the number of possible choices at each stage and r is the number of stages.

Multiplication with repetition

- Pictorial representation of multiplication with repetition.

Where n is the number of possible choices at each stage and r is the number of stages.

Multiplication with repetition

- Pictorial representation of multiplication with repetition.

Where n is the number of possible choices at each stage and r is the number of stages.

Multiplication Rule with Repetition

- Suppose a six-sided die is rolled twice.

First roll:

Second roll:

- A single outcome is an ordered pair, for example: (first roll, second roll)

(1, 4)

represented by

- There are 6 possible outcomes for the first roll and 6 possible outcomes for the second roll.
 $6 \times 6 = 6^2 = 36$

Multiplication Rule with Repetition

- Suppose a six-sided die is rolled twice.

First roll:

Second roll:

- A single outcome is an ordered pair, for example: (first roll, second roll)

(1, 4)

represented by

- There are 6 possible outcomes for the first roll and 6 possible outcomes for the second roll.
 $6 \times 6 = 6^2 = 36$

Multiplication Rule with Repetition

- Suppose a six-sided die is rolled twice.

First roll:

Second roll:

- A single outcome is an ordered pair, for example: (first roll, second roll)

(1, 4)

represented by

- There are 6 possible outcomes for the first roll and 6 possible outcomes for the second roll.
 $6 \times 6 = 6^2 = 36$

Multiplication Rule with Repetition

- Suppose a six-sided die is rolled twice.

First roll:

Second roll:

- A single outcome is an ordered pair, for example: (first roll, second roll)

(1, 4)

represented by

- There are 6 possible outcomes for the first roll and 6 possible outcomes for the second roll.
 $6 \times 6 = 6^2 = 36$

Multiplication Rule with Repetition

- Suppose a six-sided die is rolled twice.

First roll:

Second roll:

- A single outcome is an ordered pair, for example: (first roll, second roll)

(1, 4)

represented by

- There are 6 possible outcomes for the first roll and 6 possible outcomes for the second roll.
 $6 \times 6 = 6^2 = 36$

Multiplication Rule with Repetition

- Suppose a six-sided die is rolled twice.

First roll:

Second roll:

- A single outcome is an ordered pair, for example: (first roll, second roll)

(1, 4)

represented by

- There are 6 possible outcomes for the first roll and 6 possible outcomes for the second roll.
 $6 \times 6 = 6^2 = 36$

Multiplication Rule with No-Repetition

- Suppose a license plate consists of two letters followed by four digits. If no letter or digit may be repeated, how many different license plates can be formed?
- Assuming the license plate number format is:

L L D D D D

- then the number of choices at each stage is

26, 25, 10, 9, 8, 7

- Therefore, by the multiplication rule,

$$N = 26 \cdot 25 \cdot 10 \cdot 9 \cdot 8 \cdot 7 = 3,276,000.$$

Multiplication Rule with No-Repetition

- Suppose a license plate consists of two letters followed by four digits. If no letter or digit may be repeated, how many different license plates can be formed?
- Assuming the license plate number format is:

L L D D D D

- then the number of choices at each stage is

26, 25, 10, 9, 8, 7

- Therefore, by the multiplication rule,

$$N = 26 \cdot 25 \cdot 10 \cdot 9 \cdot 8 \cdot 7 = 3,276,000.$$

Multiplication Rule with No-Repetition

- Suppose a license plate consists of two letters followed by four digits. If no letter or digit may be repeated, how many different license plates can be formed?
- Assuming the license plate number format is:

L L D D D D

- then the number of choices at each stage is

26, 25, 10, 9, 8, 7

- Therefore, by the multiplication rule,

$$N = 26 \cdot 25 \cdot 10 \cdot 9 \cdot 8 \cdot 7 = 3,276,000.$$

Multiplication Rule with No-Repetition

- Suppose a license plate consists of two letters followed by four digits. If no letter or digit may be repeated, how many different license plates can be formed?
- Assuming the license plate number format is:

L L D D D D

- then the number of choices at each stage is

26, 25, 10, 9, 8, 7

- Therefore, by the multiplication rule,

$$N = 26 \cdot 25 \cdot 10 \cdot 9 \cdot 8 \cdot 7 = 3,276,000.$$

Multiplication Rule with No-Repetition

- Suppose a license plate consists of two letters followed by four digits. If no letter or digit may be repeated, how many different license plates can be formed?
- Assuming the license plate number format is:

L L D D D D

- then the number of choices at each stage is

26, 25, 10, 9, 8, 7

- Therefore, by the multiplication rule,

$$N = 26 \cdot 25 \cdot 10 \cdot 9 \cdot 8 \cdot 7 = 3,276,000.$$

Multiplication Rule with No-Repetition

- Suppose a license plate consists of two letters followed by four digits. If no letter or digit may be repeated, how many different license plates can be formed?
- Assuming the license plate number format is:

L L D D D D

- then the number of choices at each stage is

26, 25, 10, 9, 8, 7

- Therefore, by the multiplication rule,

$$N = 26 \cdot 25 \cdot 10 \cdot 9 \cdot 8 \cdot 7 = 3,276,000.$$

Multiplication Rule with No-Repetition (Cont'd)

- The no repetition case can be shown as:

$$n \times (n - 1) \times (n - 2) \times \dots \times (n - r + 1) = \frac{n!}{(n - r)!} = {}_n P_r$$

Section 4

Addition Rule

Addition Rule

- The **multiplication rule** applies when a process consists of successive stages. In contrast, some counting problems might involve alternative or mutually exclusive ways of completing a task.
- Such are solved using the **Addition Rule**.

Theorem 3. Addition Rule.

If one task can be performed in n_1 ways and another mutually exclusive task can be performed in n_2 ways, then there are

$$n_1 + n_2$$

ways of performing either the first task or the second task.

Addition Rule (Cont'd)

A student may choose one elective from either:

- 6 Economics courses, *or*
- 4 Mathematics courses.

Using the addition rule,

$$6 + 4 = 10$$

Therefore, the student has **10 possible choices**.

- **Key idea: OR → Add**
- **AND → Multiply**

Multiplication and Addition Rule

Example:

Suppose a family from Barbados is planning a cruise and may depart from either Jamaica or Miami. If the family departs from Jamaica, only JetBlue and Caribbean Airlines are available. If the family departs from Miami, JetBlue, American Airlines, Delta, and Caribbean Airlines are available. How many different home-port–airline travel arrangements are possible?

Solution

- If Jamaica is selected, the airline can be chosen in $n_2 = 2$ ways. Therefore the Jamaica route produces

$$1 \times 2 = 2$$

- possible home-port-airline arrangements.

Multiplication and Addition Rule

- If the Miami route is selected, the airline can be chosen in $n_2 = 4$ ways. Therefore, the Miami route produces

$$1 \times 4 = 4$$

- possible home-port-airlines arrangements.
- Since the traveller can choose the **Jamaica route or the Miami route**, the number of possibilities across the two mutually exclusive routes is

$$2 + 4 = 6.$$

- Thus, there are **6 possible home-port-airline arrangements**.

Multiplication and Addition Rule

The tree diagram for the *restricted* case is shown below.

$JB = \text{JetBlue}$ $AA = \text{American Airlines}$ $DL = \text{Delta}$ $CAL = \text{Caribbean Airlines}$

$$n_J + n_M = 2 + 4 = 6 \text{ possible travel arrangements}$$

Section 5

Permutation

Permutation

- There are many counting problems in which we are interested in the different ways a set of objects can be ordered or arranged.
- Such counting problems are called **Permutations**

Permutation

A **permutation** is an ordered arrangement of n different elements of a set.

For k objects selected from n distinct objects without repetition,

$${}_nP_k = \frac{n!}{(n-k)!}$$

If all n objects are arranged,

$$n!$$

Permutation

- There are many counting problems in which we are interested in the different ways a set of objects can be ordered or arranged.
- Such counting problems are called **Permutations**

Permutation

A **permutation** is an ordered arrangement of n different elements of a set.

For k objects selected from n distinct objects without repetition,

$${}_nP_k = \frac{n!}{(n-k)!}$$

If all n objects are arranged,

$$n!$$

Permutation

- There are many counting problems in which we are interested in the different ways a set of objects can be ordered or arranged.
- Such counting problems are called **Permutations**

Permutation

A **permutation** is an ordered arrangement of n different elements of a set.

For k objects selected from n distinct objects without repetition,

$${}_nP_k = \frac{n!}{(n-k)!}$$

If all n objects are arranged,

$$n!$$

Linear Permutation

Example

How many permutations are there of the letters a, b and c?

[1] "abc" "acb" "cab" "cba" "bca" "bac"

Theorem 4. Linear Permutation. The number of permutations of n distinct objects is $n!$.

where,

$$n! = n \times (n - 1) \times (n - 2) \times \dots \times 2 \times 1$$

for $n \geq 1$, with

$$0! = 1.$$

Linear Permutation

Example

How many permutations are there of the letters a, b and c?

[1] "abc" "acb" "cab" "cba" "bca" "bac"

Theorem 5. Linear Permutation. The number of permutations of n distinct objects is $n!$.

where,

$$n! = n \times (n - 1) \times (n - 2) \times \dots \times 2 \times 1$$

for $n \geq 1$, with

$$0! = 1.$$

Linear Permutation

Example

How many permutations are there of the letters a, b and c?

[1] "abc" "acb" "cab" "cba" "bca" "bac"

Theorem 6. Linear Permutation. The number of permutations of n distinct objects is $n!$.

where,

$$n! = n \times (n - 1) \times (n - 2) \times \dots \times 2 \times 1$$

for $n \geq 1$, with

$$0! = 1.$$

Linear Permutation (Cont'd)

- In the previous example, $n!$ counts the number of **linear permutation of n distinct objects** when all n objects are arranged.
- For the example with (a,b and c),

$$3! = (3 \cdot 2 \cdot 1) = 6$$

- giving

```
[1] "abc" "acb" "cab" "cba" "bca" "bac"
```

Linear Permutation (Cont'd)

- In the previous example, $n!$ counts the number of **linear permutation of n distinct objects** when all n objects are arranged.
- For the example with (a,b and c),

$$3! = (3 \cdot 2 \cdot 1) = 6$$

- giving

```
[1] "abc" "acb" "cab" "cba" "bca" "bac"
```

Linear Permutation (Cont'd)

Section 6

Circular Permutation

Circular Permutation

- A permutation in which objects are arranged around a circle is called a **circular permutation**
- Two circular permutations are not considered different and are counted only once if corresponding objects in the two arrangements have **same objects to their left and to their right**.

Theorem 7. Circular Permutation.

The number of permutations of n distinct objects arranged in a circle is

$$(n - 1)!$$

Circular Permutation

Circular permutations of n objects

$$(n - 1)! = (4 - 1)! = 3! = 6$$

Permutations of r objects chosen from n distinct objects

Let us look at the case of ***Permutation of r objects chosen from n distinct objects.***

Theorem 8. Permutation of r objects chosen from n distinct objects.

The number of permutations of n distinct objects taken r at a time is

$${}_nP_r = \frac{n!}{(n-r)!}$$

for $r = 0, 1, 2, \dots, n$.

Permutations of r objects chosen from n distinct objects

Let us look at the case of *Permutation of r objects chosen from n distinct objects.*

Theorem 9. Permutation of r objects chosen from n distinct objects.

The number of permutations of n distinct objects taken r at a time is

$${}_nP_r = \frac{n!}{(n-r)!}$$

for $r = 0, 1, 2, \dots, n$.

Permutations of r objects chosen from n distinct objects

Understanding the Permutation function

$${}_nP_r = \frac{n!}{(n-r)!}$$

for $r = 0, 1, 2, \dots, n$.

where:

- n is the total number of distinct objects available.
- P is the permutation symbol
- r is the number of objects selected and arranged.
- The expression read:

n permute r

Permutations of r objects chosen from n distinct objects

Quick example,

$${}_5P_3$$

is read as:

“five permute three”

and means:

How many ordered arrangements of 3 objects can be formed from 5 distinct objects?

Using the formula,

$${}_5P_3 = \frac{5!}{(5-3)!} = \frac{5!}{2!} = 5 \times 4 \times 3 = 60$$

Permutations of r objects chosen from n distinct objects

Understanding the mechanics of permutation

Let us assume we have five letters,

$$A, B, C, D, E$$

How many ways can we select a group of 3 letters?

[1] "ABC" "ABD" "ABE" "ACD" "ACE" "ADE" "BCD" "BCE" "BDE" "CDE"

We see here that we can select 10 combination of 3 objects from the five.

$$\binom{5}{3} = \frac{5!}{3!2!} = 10$$

Permutations of r objects chosen from n distinct objects

Let us permute one of the combinations say

A, B, C

$$3! = 3 \times 2 \times 1 = 6$$

	[,1]	[,2]	[,3]

[25]	"CAB"	"CAD"	"CAE"	"CBA"	"CBD"	"CBE"	"CDA"	"CDB"	"CDE"	"CEA"	"CEB"	"CED"
[37]	"DAB"	"DAC"	"DAE"	"DBA"	"DBC"	"DBE"	"DCA"	"DCB"	"DCE"	"DEA"	"DEB"	"DEC"
[49]	"EAB"	"EAC"	"EAD"	"EBA"	"EBC"	"EBD"	"ECA"	"ECB"	"ECD"	"EDA"	"EDB"	"EDC"

Permutations of r objects chosen from n distinct objects

Example

- Consider eight athletes competing in the women's 100 meter finals at the Paris Olympics. In how many different ways can the gold, silver and bronze medals be awarded?
- Let's use the names of the actual finalists,

$$S = \{JA, SR, MJ, DN, TT, MK, TC, MT\}$$

- which corresponds to Julien Alfred, Sha' Carri Richardson, Melissa Jefferson, Daryll Neita, Twanisha Terry, Mujinga Kambundji, Tia Clayton and Marie-Josée Ta Lou-Smith.
- This a permutation case, since the order matters. Because:

$$(JA, SR, MJ) \neq (SR, JA, MJ)$$

Permutations of r objects chosen from n distinct objects

- **Step 1: Choose the Gold Medalist**

Any one of the eight athletes can finish first.

$$n = \boxed{8}$$

- **Step 2: Choose the Silver Medalist**

Once an athlete has received a gold medal they cannot receive a silver medal - this is a mutually exclusive event

$$n - 1 = 8 - 1 = \boxed{7}$$

- **Step 3: Choose the Bronze Medalist**

$$n - 2 = 8 - 2 = \boxed{6}$$

Permutations of r objects chosen from n distinct objects

For the women's 100 meter finals,

$$n = 8 \text{ and } r = 3$$

The result of 8 permute 3 is:

$${}_8P_3 = \frac{8!}{(8-3)!} = \frac{8!}{5!}$$

Since $8! = 8 \times 7 \times 6 \times 5!$. We cancel the $5!$.

Therefore,

$${}_8P_3 = 8 \times 7 \times 6 = \boxed{336}$$

There are 336 permutations of how the podium positions can be given.

Permutation

PODIUM

*Only the order of the top 3 finishers matters for the medals – swapping who wins Gold and Silver between runners 3 and 2 would produce a different outcome. This is why we count **permutations**, not combinations.*

$$P_3^8 = \frac{8!}{(8-3)!} = 8 \times 7 \times 6 = 336 \text{ possible Gold/Silver/Bronze outcomes}$$

Permutations of a Multiset

A **multiset** is a collection in which some objects may be identical or repeated.

Consider the following five suit labels:

$$\{\heartsuit_1, \heartsuit_2, \spadesuit_1, \spadesuit_2, \clubsuit_1\}$$

There are **5 objects**, but only **3 distinct types** of objects:

$$n_{\heartsuit} = 2, \quad n_{\spadesuit} = 2, \quad n_{\clubsuit} = 1.$$

If all five objects were distinct, there would be

$$5! = 120$$

possible arrangements.

Permutation of Multisets

However, interchanging identical suit symbols does **not** create a new arrangement.

$$\{\heartsuit_1, \heartsuit_2, \spadesuit_1, \spadesuit_2, \clubsuit_1\} = \{\heartsuit_2, \heartsuit_1, \spadesuit_2, \spadesuit_1, \clubsuit_1\}$$

Therefore, the number of distinct permutations is

$$\frac{5!}{2!2!1!} = \frac{120}{4} = \boxed{30}.$$

Key idea: In a multiset permutation, **order matters**, but **identical objects are indistinguishable**.

Permutation with Repeated or identical objects.

Theorem

Theorem 10. Permutation with Repeated or Identical Objects.

The number of permutations of n objects of which n_1 are of one kind, n_2 are of a second kind, $\dots, n_k$ are of a k th kind and $n_1 + n_2 + \dots + n_k = n$ is

$$\frac{n!}{n_1! \cdot n_2! \cdot \dots \cdot n_k!}$$

Permutation with Multisets

Example

A student receives five CSEC examination grades, three Grade 1s and two Grade 2s. In how many distinct ways can these grades be assigned across five different subjects?

Solution:

- The multi-set of grades is

$$\{1, 1, 1, 2, 2\}$$

- There are 5 observations in total, multiplicities

$$n_1 = 3, \quad n_2 = 2.$$

Permutation with Multisets

So the number of distinct permutations is

$$\frac{5!}{3!2!} = \frac{120}{12} = \boxed{10}.$$

How many distinct arrangements can be formed from the letters in the word STATISTICS?

[1] 50400

So the number of distinct permutations is

$$\frac{5!}{3!2!} = \frac{120}{12} = \boxed{10}.$$

How many distinct arrangements can be formed from the letters in the word STATISTICS?

[1] 50400

Permutations: Cheat Sheet

Type	Formula	When to Use
Linear permutation	$n!$	Arrange all n distinct objects
Permutation of r from n	${}_nP_r = \frac{n!}{(n-r)!}$	Select and arrange r objects from n distinct objects
Permutation with identical objects	$\frac{n!}{n_1!n_2!\cdots n_k!}$	Some objects are repeated or indistinguishable
Permutation with repetition allowed	n^r	There are r ordered stages and n choices at each stage
Circular permutation	$(n-1)!$	Arrange n distinct objects around a circle

Quick Decision Rule

- All n distinct objects arranged? $\rightarrow n!$
- Choose and arrange r from n ? $\rightarrow {}_n P_r$
- Some objects identical? $\rightarrow \frac{n!}{n_1! n_2! \cdots n_k!}$
- Repetition allowed? $\rightarrow n^r$
- Circular arrangement? $\rightarrow (n - 1)!$

Section 7

Combinations

What is a combination?

- There are many cases where one is interested in determining the number of ways in which r objects can be selected from among n distinct objects **without** regard to the order in which they are selected.
- This is referred to as a **combination**.

Combination

A **combination** is a selection of r objects taken from n distinct objects without regard to the order of selection.

- **Note:** combination is an r combination corresponding to an r element subset.

What is a combination?

- This is referred to as a **combination**.

Combination

A **combination** is a selection of r objects taken from n distinct objects without regard to the order of selection.

- **Note:** combination is an r combination corresponding to an r element subset.

Combinations

- **Remember** a combination is an r combination corresponding to an r element subset.
- If you have $r = 3$ and $n = 5$. **How many combinations can you derive?**

Choose $r=3$ objects from $n=5$ distinct objects

Order does not matter: $ABC = ACB = BAC$

Combinations

- **Remember** a combination is an r combination corresponding to an r element subset.
- If you have $r = 3$ and $n = 5$. **How many combinations can you derive?**

Choose $r=3$ objects from $n=5$ distinct objects

- If you have $r = 3$ and $n = 5$. **How many combinations can you derive?**

Choose $r=3$ objects from $n=5$ distinct objects

Order does not matter: $ABC = ACB = BAC$

Theorem 11. Combination. The number of **combinations** of n distinct objects taken r at a time is:

$$\binom{n}{r} = \frac{n!}{r!(n-r)!}$$

where n is the number of distinct objects in the set and r is the number of objects selected from n , with $0 \leq r \leq n$,
for

$$r = 0, 1, 2, \dots, n$$

Combination

Example:

In how many different ways can a person gathering data for a market research organization select three of the 20 households living in a certain apartment complex?

Solution

Let the three household be defined as:

$$\{H_1, H_2, H_3\}$$

Rearranging the group as

$$\{H_3, H_2, H_1\}$$

does not create a different combination because **order does not matter**.

We apply the combination formula:

$$\binom{n}{r} = \frac{n!}{r!(n-r)!}$$

There are,

$$n = 20, \quad r = 3$$

Therefore,

$$\binom{20}{3} = \frac{20!}{3!(20-3)!} = \frac{6840}{6} = 1140$$

There are 1,140 different ways to select three households from the 20 households.

If the example was a permutation problems. What would be the answer?

[1] 6840

Why?

[1] 6840

Why?

If the example was a permutation problems. What would be the answer?

[1] 6840

Why?

Section 8

Partitioning

Partitioning

What is a Partition?

- A combination of r objects chosen from n distinct objects can be viewed as a partition of the n objects into two groups: **the r selected objects and the $n - r$ objects not selected.**

Theorem 12. Partition. The number of ways in which a set of n distinct objects can be partitioned into k subsets with n_1 objects in the first subset, n_2 objects in the second subset, ... , and n_k objects in the k -th subset is:

$$\binom{n}{n_1, n_2, \dots, n_k} = \frac{n!}{n_1! \times n_2! \times \dots \times n_k!}$$

subject to

$$n_1 + n_2 + \dots + n_k = n.$$

Example:

In how many ways can a set of four objects be partitioned into three subsets containing, respectively, two, one and one of the objects?

Solution

Let the four distinct objects be described as the following set.

$$S = \{A, B, C, D\}$$

We want three subsets (2, 1, 1):

$$S_1 : 2 \text{ objects, } S_2 : 1 \text{ object, } S_3 : 1 \text{ object}$$

Step 1:

Choose the two objects for the first subset.

We choose 2 of the 4 objects:

$$\binom{4}{2} = 6$$

For example, let us assume the first sub-set is:

$$S_1 = \{A, B\}$$

Partitioning

Step 2:

Choose one of the remaining objects for the second subset.

After selecting a and b , two objects remain:

$$\{C, D\}$$

Choose 1 object out of the 2:

$$\binom{2}{1} = 2$$

Say we selected D .

$$S_2 = \{D\}$$

Step 3:

The last object goes into the 3rd and last subset.

Only one object d remains. Therefore,

$$\begin{pmatrix} 1 \\ 1 \end{pmatrix} = 1$$

By the multiplication principle,

$$\begin{pmatrix} 4 \\ 2 \end{pmatrix} \begin{pmatrix} 2 \\ 1 \end{pmatrix} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = 6 \times 2 \times 1 = \boxed{12}$$

The three counting steps can be written compactly using the **multinomial coefficient** expression:

$$\binom{4}{2, 1, 1} = \frac{4!}{2!1!1!} = 12$$

Partitioning

Suppose $S = \{a, b, c, d\}$ is partitioned into three labelled subsets of sizes 2, 1, and 1.

The possible partitions are:

$ab \mid c \mid d$	$ab \mid d \mid c$	$ac \mid b \mid d$	$ac \mid d \mid b$
$ad \mid b \mid c$	$ad \mid c \mid b$	$bc \mid a \mid d$	$bc \mid d \mid a$
$bd \mid a \mid c$	$bd \mid c \mid a$	$cd \mid a \mid b$	$cd \mid b \mid a$

Therefore, $\frac{4!}{2!1!1!} = \boxed{12}$.

Section 9

Binomial Coefficients

Binomial Coefficients

- A binomial coefficient gives the number of ways to choose r objects from n distinct objects when order does not matter.
- It is written as

$$\binom{n}{r}$$

- The term **binomial coefficient** comes from the expansion of binomial expressions in algebra. A binomial is an algebraic expression containing two terms, such as

$$(x + y)$$

Binomial Coefficients

Example:

Consider

$$(x + y)^3$$

This means,

$$(x + y)^3 = (x + y)(x + y)(x + y).$$

Expanding term by term gives

$$\begin{aligned}(x + y)^3 &= x \cdot x \cdot x + x \cdot x \cdot y + x \cdot y \cdot x + x \cdot y \cdot y \\ &\quad + y \cdot x \cdot x + y \cdot x \cdot y + y \cdot y \cdot x + y \cdot y \cdot y.\end{aligned}$$

Binomial Coefficients

Simplifying each product,

$$(x + y)^3 = x^3 + x^2y + x^2y + xy^2 \\ + x^2y + xy^2 + xy^2 + y^3.$$

Collecting like terms,

$$(x + y)^3 = x^3 + \underbrace{(x^2y + x^2y + x^2y)}_{3 \text{ terms}} + \underbrace{(xy^2 + xy^2 + xy^2)}_{3 \text{ terms}} + y^3.$$

Hence,

$$\boxed{(x + y)^3 = x^3 + 3x^2y + 3xy^2 + y^3}.$$

Binomial Coefficients

The coefficients

$$1, \quad 3, \quad 3, \quad 1$$

arise from the number of ways of choosing which of the three factors contribute a y .

For example, the term x^2y can arise in three different ways:

$$xxy, \quad xyx, \quad yxx.$$

Therefore,

$$\binom{3}{1} = 3.$$

Similarly, the term xy^2 can arise as

$$xyy, \quad yxy, \quad yyx.$$

Therefore,

$$\binom{3}{2} = 3.$$

Binomial Coefficients

Choosing the y -Factors

A useful way to interpret the coefficients is to ask how many of the three factors are selected to contribute a y . For example, $(x + y)^3$, the possibilities are:

Number of y 's selected, r	Resulting Term	Number of Ways
0	x^3	$\binom{3}{0} = 1$
1	x^2y	$\binom{3}{1} = 3$
2	xy^2	$\binom{3}{2} = 3$
3	y^3	$\binom{3}{3} = 1$

Thus,

$$(x + y)^3 = \binom{3}{0}x^3 + \binom{3}{1}x^2y + \binom{3}{2}xy^2 + \binom{3}{3}y^3.$$

The binomial theorem can be written as

$$(x + y)^n = \sum_{r=0}^n \binom{n}{r} x^{n-r} y^r$$

Binomial Theorem

For example, when $n = 3$,

$$(x + y)^3 = \sum_{r=0}^3 \binom{3}{r} x^{3-r} y^r$$

which expands to

$$(x + y)^3 = \binom{3}{0} x^3 + \binom{3}{1} x^2 y + \binom{3}{2} x y^2 + \binom{3}{3} y^3$$

and therefore,

$$(x + y)^3 = x^3 + 3x^2 y + 3x y^2 + y^3.$$

Theorem 13. The Binomial Theorem.

For any positive integer n ,

$$(x + y)^n = \sum_{r=0}^n \binom{n}{r} x^{n-r} y^r$$

where

$$\binom{n}{r} = \frac{n!}{r!(n-r)!}.$$

- **Note:** this is the building blocks for the binomial probability distribution.

Binomial Coefficients

Why Binomial Coefficients Matter?

Binomial coefficients are one of the **building blocks of the binomial probability distribution**.

$$P(X = r) = \binom{n}{r} p^r (1 - p)^{n-r}$$

The term

$$\binom{n}{r}$$

counts the number of ways r successes can occur in n trials.

Key idea: Binomial coefficients count the possible arrangements of successes.

Binomial Coefficient

Example

Expanding $(a + b)^4$

Consider

$$(a + b)^4.$$

Its expansion is

$$(a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4.$$

Binomial Coefficients

The coefficients are

$$1, \quad 4, \quad 6, \quad 4, \quad 1.$$

These are precisely

$$\binom{4}{0} = 1, \quad \binom{4}{1} = 4, \quad \binom{4}{2} = 6, \quad \binom{4}{3} = 4, \quad \binom{4}{4} = 1.$$

Therefore,

$$(a + b)^4 = \binom{4}{0} a^4 + \binom{4}{1} a^3 b + \binom{4}{2} a^2 b^2 + \binom{4}{3} a b^3 + \binom{4}{4} b^4.$$

Section 10

Symmetry Property of Binomial Coefficients

Symmetry Property of Binomial Coefficients

Binomial Coefficients have a very interesting property called **symmetry property**.

Theorem 14. Symmetry Property of Binomial Coefficients. For any positive integer n and $r = 1, 2, \dots, n - 1$,

$$\binom{n}{r} = \binom{n}{n-r}$$

Symmetry Property of Binomial Coefficients

Example:

A committee of 3 students is to be selected from a class of 8 students. Show, using the symmetry property of binomial coefficients, that selecting the 3 students for the committee is equivalent to selecting the 5 students who will not serve on the committee.

Solution

Using combinations,

$$\binom{8}{3} = 56$$

Binomial Coefficient

By symmetry,

$$\binom{8}{3} = \binom{8}{8-3} = \binom{8}{5} = 56$$

So,

$$\boxed{\binom{8}{3} = \binom{8}{5}} = 56$$

because choosing the 3 students who are included automatically determines the 5 students who are excluded.

Binomial Coefficients

Proof of the Symmetry Property of Binomial Coefficients

The theorem states that,

$$\begin{aligned}\binom{n}{r} &= \binom{n}{n-r} \\ \binom{n}{n-r} &= \frac{n!}{(n-r)![n-(n-r)]!} \\ &= \frac{n!}{(n-r)![n-n+r]!} \\ &= \frac{n!}{(n-r)!r!} = \binom{n}{r}\end{aligned}$$

Binomial Coefficient

Example

Given $\binom{4}{0} = 1$, $\binom{4}{1} = 4$, and $\binom{4}{2} = 6$, find $\binom{4}{3}$ and $\binom{4}{4}$

Using symmetry,

$$\binom{n}{r} = \binom{n}{n-r}$$

So:

$$\binom{4}{3} = \binom{4}{4-3} = \binom{4}{1} = 4.$$

$$\binom{4}{4} = \binom{4}{4-4} = \binom{4}{0} = 1.$$

Section 11

Pascal's Triangle

Pascal's Triangle

Pascal's Triangle is a triangular arrangement of binomial coefficients. Each corresponds to a value of n and the entries in row n are:

$$\binom{n}{0}, \binom{n}{1}, \dots, \binom{n}{n}$$

The first few rows are:

$$\begin{array}{ccccccc} & & & & 1 & & \\ & & & 1 & & 1 & \\ & & 1 & & 2 & & 1 \\ & 1 & & 3 & & 3 & & 1 \\ 1 & & 4 & & 6 & & 4 & & 1 \end{array}$$

Pascal's Triangle

The rows of Pascal's triangle give the coefficients in the expansion of $(x + y)^n$.

$$(x + y)^0 = 1$$

$$(x + y)^1 = x + y$$

$$(x + y)^2 = x^2 + 2xy + y^2$$

$$(x + y)^3 = x^3 + 3x^2y + 3xy^2 + y^3$$

$$(x + y)^4 = x^4 + 4x^3y + 6x^2y^2 + 4xy^3 + y^4$$

Pascal's Triangle

The corresponding rows of Pascal's triangle are:

$$n = 0 : \quad 1$$

$$n = 1 : \quad 1 \quad 1$$

$$n = 2 : \quad 1 \quad 2 \quad 1$$

$$n = 3 : \quad 1 \quad 3 \quad 3 \quad 1$$

$$n = 4 : \quad 1 \quad 4 \quad 6 \quad 4 \quad 1$$

Pascal's Triangle and the Binomial Expansion

				1				
				1		1		
			1		2		1	
		1		3		3		1
	1		4		6		4	
1		4		6		4		1

$$(x + y)^0 = 1$$

$$(x + y)^1 = x + y$$

$$(x + y)^2 = x^2 + 2xy + y^2$$

$$(x + y)^3 = x^3 + 3x^2y + 3xy^2 + y^3$$

$$(x + y)^4 = x^4 + 4x^3y + 6x^2y^2 + 4xy^3 + y^4$$

Each row of Pascal's triangle gives the coefficients in the expansion of $((x + y)^n)$.

Section 12

Lecture Recap

Lecture 1 Recap: Counting Rules

Multiplication Rule

Use when a process occurs through **successive stages**.

$$N = n_1 n_2 \cdots n_k$$

If there are n choices at each of r stages and repetition is allowed,

$$N = n^r$$

Addition Rule

Use when there are **alternative, mutually exclusive ways** of completing a task.

$$N = n_1 + n_2 + \cdots + n_k$$

[AND $\rightarrow$ Multiply OR $\rightarrow$ Add]

Lecture 1 Recap: Counting Rules

Permutation, Combination or Partition?

Problem	Key Question	Formula
Permutation	Does order matter?	${}_nP_r = \frac{n!}{(n-r)!}$
Linear Permutation	Arrange all n distinct objects?	$n!$
Repeated Objects	Are some objects identical?	$\frac{n!}{n_1!n_2!\cdots n_k!}$
Combination	Does order <i>not</i> matter?	$\binom{n}{r} = \frac{n!}{r!(n-r)!}$
Partition	Divide objects among specified groups?	$\frac{n!}{n_1!n_2!\cdots n_k!}$

Permutation = Selection + Arrangement

Combination = Selection Only

Lecture 1 Recap: Counting Rules

A binomial coefficient is written

$$\binom{n}{r}$$

and counts the number of ways to choose r objects from n when **order does not matter**.

Symmetry Property

$$\boxed{\binom{n}{r} = \binom{n}{n-r}}$$

Lecture 1 Recap: Counting Rules

Binomial Theorem

$$(x + y)^n = \sum_{r=0}^n \binom{n}{r} x^{n-r} y^r$$

Pascal's Triangle

$$\begin{array}{ccccccc} & & & & 1 & & & \\ & & & & & & 1 & \\ & & & 1 & & 2 & & 1 \\ & & 1 & & 3 & & 3 & & 1 \\ & 1 & & 4 & & 6 & & 4 & & 1 \end{array}$$

Row n contains the coefficients in the expansion of $(x + y)^n$.

What Should You Be Able to Do?

Before solving a counting problem, ask:

- ① Is the process made up of **successive stages**?
- ② Are there **alternative routes**?
- ③ Is **repetition allowed**?
- ④ Does **order matter**?
- ⑤ Are all objects **distinct**, or are some identical?
- ⑥ Am I **selecting**, **arranging**, or **partitioning**?
- ⑦ Can I interpret $\binom{n}{r}$ rather than simply calculate it?
- ⑧ Can I connect combinations to **binomial coefficients** and **Pascal's triangle**?

Identify the counting experiment first; then choose the formula.
